

### ✓ 03.03 chebyshev

so that green line is the degree  $n - 1$  interpolating polynomial. useful, isnt it?

### ✓ 1 chebyshevs theorem

lagrange is simple, newtons divided difference is simpler in implementation and chebyshev is an implementation designed to improve control of the interpolation error.

$$\frac{(x - x_1)(x - x_2) \dots (x - x_n)}{n!} f^{(n)}(c)$$

on the interpolation interval. thats not everything but its a start.

consider interval  $[-1, 1]$ . note that numerator is degree  $n$  polynomial with maximum on that interval. is there particular  $x_1, \dots, x_n$  to cause the maximum error to be as small as possible? this is the minimax problem of interpolation.

### ✓ code, visual, polynomial interpolation error

```
1 import matplotlib.pyplot as plt
2 import numpy as np
3 from numpy import polynomial as npp
4
5 def err_num(x,xs): # ~ horners~
10
11 def main():~
41
42 if __name__ == "__main__":~
44
```

## polynomial interpolation error

### theorem 06 chebyshev interpolation

the choice of  $x_i \in [-1, 1]$  that makes the value of

$$\max_{x \in [-1, 1]} |(x - x_1) \dots (x - x_n)|$$

as small as possible is

$$x_i = \cos \frac{(2i-1)\pi}{2n} \quad i = 1, \dots, n,$$

and its minimum is  $\frac{1}{2^{n-1}}$ . so the minimum is achieved by

$$(x - x_1) \dots (x - x_n) = \frac{1}{2^{n-1}} T_n(x),$$

where  $T_n(x)$  denotes degree  $n$  chebyshev polynomial.

ie, interpolation error can be minimized if the  $n$  interpolation base points in  $[-1, 1]$  are chosen to be the roots of the degree  $n$  chebyshev interpolating polynomial  $T_n(x)$ . these roots are

$$x_i = \cos \frac{\text{odd } \pi}{2n}$$

where "odd" stands for the odd numbers from 1 to  $2n - 1$ . that guarantees the absolute value of the error term numerator is less than  $\frac{1}{2^{n-1}}$  for all  $x \in [-1, 1]$ .

choosing the chebyshev roots as the base points for interpolation distributes the interpolation error as evenly as possible across the interval  $[-1, 1]$ . the interpolating polynomial that uses chebyshev roots as base points is the **chebyshev interpolating polynomial**.

### example 10

find worst-case error bound for the difference on  $[-1, 1]$  between  $f(x) = e^x$  and degree four chebyshev interpolating polynomial.

$$\text{error } \epsilon(x) = f(x) - P_4(x) = \frac{(x - x_1)(x - x_2)(x - x_3)(x - x_4)(x - x_5)}{5!} f^{(5)}(c),$$

where

$$x_1 = \cos \frac{\pi}{10}, x_2 = \cos \frac{3\pi}{10}, x_3 = \cos \frac{5\pi}{10}, x_4 = \cos \frac{7\pi}{10}, x_5 = \cos \frac{9\pi}{10}$$

are the chebyshev roots and where  $-1 \leq c \leq 1$ . by theorem 05, for  $-1 \leq x \leq 1$ ,

$$|(x - x_1) \dots (x - x_5)| \leq \frac{1}{2^4}.$$

also  $|f^{(5)}| \leq e^1$  on  $[-1, 1]$  and interpolation error is

$$|e^x - P_4(x)| \leq \frac{e}{2^4 \cdot 5!} \approx 0.00142 \quad \forall x \in [-1, 1].$$

programmatically, chebyshev has slightly worse error in the middle and much better error at the end points.

## ✓ 2. chebyshev polynomials

define the  $n$ th **chebyshev polynomial** by  $T_n(x) = \cos(n \arccos x)$ . work through the trig, and itll look more conventional.

$$\begin{aligned} n = 0 & \mapsto T_0(x) = \cos(0 \cdot \arccos x) = 1 \\ n = 1 & \mapsto T_1(x) = \cos(1 \cdot \arccos x) = x \\ n = 2 & \mapsto T_2(x) = \cos(2 \cdot \arccos x) = \cos^2 y, \quad \text{where } y = \arccos x \\ & = \cos^2 y - \sin^2 y - 1 \\ & = 2x^2 - 1 \quad \sim \text{degree 2 polynomial. } \checkmark \end{aligned}$$

in general,

$$\begin{aligned} T_{n+1}(x) &= \cos(n+1)y = \cos(ny + y) = \cos ny \cos y - \sin ny \sin y \\ T_{n-1}(x) &= \cos(n-1)y = \cos(ny - y) = \cos ny \cos y - \sin ny \sin(-y) \\ &\Downarrow \quad \sin(-y) = -\sin y \\ T_{n+1}(x) + T_{n-1}(x) &= 2 \cos ny \cos y \\ &\Downarrow \quad y = \arccos x \\ &= 2 \cdot T_n(x) \cdot x = 2xT_n(x) \\ &\Downarrow \\ T_{n+1}(x) &= 2xT_n(x) - T_{n-1}(x). \end{aligned}$$

this is the **recursion relation** for chebyshev polynomials.

### ✓ fact 01

$T_n$ s are polynomials. this was shown explicitly for  $T_0, T_1, T_2$  and  $T_3 = 2xT_2(x) - T_1(x) = 2x(2x^2 - 1) - x = 4x^3 - 3x$ . usw.

### ✓ fact 02

$\deg(T_n) = n$  and leading coefficient is  $2^{n-1}$ . this is clear for  $n = 1, n = 2$  and by recursion relation to all  $n$ .

✓ code, visual, chebyshev polynomial degrees

```
1 import matplotlib.pyplot as plt
2 import numpy as np
3 from numpy import polynomial as npp
4
5 def main():
6     t0 = lambda x: 1 #!o!
7     t1 = lambda x: x
8     t2 = lambda x: 2*pow(x,2) - 1
```

chebyshev polynomials

✓ fact 03

$T_n(1) = 1, T_n(-1) = (-1)^n$ . clear for  $n = 1, 2$  and in general,

$$T_{n+1}(1) = 2(1)T_n(1) - T_{n-1}(1) = 2(1) - 1 = 1 \text{ and}$$

$$\begin{aligned} T_{n+1}(-1) &= 2(-1)T_n(-1) - T_{n-1}(-1) \\ &= -2(-1) - (-1)^{n-1} \\ &= (-1)^{n-1}(2 - 1) = (-1)^{n-1} = (-1)^{n+1}. \end{aligned}$$

✓ fact 04

maximum absolute value of  $T_n(x)$  for  $-1 \leq x \leq 1$  is 1. bc  $T_n(x) = \cos y$  for some  $y$ .

✓ fact 05

all zeros of  $T_n(x)$  are located between  $-1$  and  $1$ . the zeros are solutions of  $0 = \cos(n \arccos x)$ . bc  $\cos y = 0$  iff  $y = \text{odd integer} \cdot (\frac{\pi}{2})$ ,

$$\begin{aligned} n \arccos x &= \text{odd} \cdot \frac{\pi}{2} \\ x &= \cos \frac{\text{odd} \cdot \pi}{2n}. \end{aligned}$$

✓ visual, chebyshev root spacing

```
1 import matplotlib.pyplot as plt
2 import numpy as np
3
4 def main():
5
6     fig, axes = plt.subplots(1, 3)
7     fig.suptitle('Chebyshev roots')
8     # Plot roots for T0, T1, T2, T3, T4, T5
```

#### fact 06

$T_n(x)$  alternates between  $-1$  and  $1$  a total of  $n + 1$  times. this happens at  $\cos 0, \cos \frac{\pi}{n}, \dots, \cos(n-1)\frac{\pi}{n}, \cos \pi$ .

#### usw

$\frac{T_n(x)}{2^{n-1}}$  is [monic](#) from fact 02. all roots of  $T_n(x)$  are real from fact 05. so  $\frac{T_n(x)}{2^{n-1}}$  in factored form is  $(x - x_1) \dots (x - x_n)$  where  $x_i$  are chebyshev nodes as described in theorem 08.

#### proof of theorem 06

let  $P_n(x)$  be a monic polynomial with an even smaller absolute maximum on  $[-1, 1]$ ; ie,  $|P_n(x)| < \frac{1}{2^{n-1}}$  for  $-1 \leq x \leq 1$ . this assumption leads to a contradiction. bc  $T_n(x)$  alternates between  $-1$  and  $1$  a total of  $n + 1$  times (fact 06), at these  $n + 1$  points the difference  $P_n - T_n/2^{n-1}$  is alternately positive and negative. therefore,  $P_n - T_n/2^{n-1}$  must cross zero at least  $n$  times; that is, it must have at least  $n$  roots. this contradicts the fact that, because  $P_n, T_n/2^{n-1}$  are monic, their difference is of degree  $\leq n - 1$ . ■

### 3. change of interval

so far our discussion of chebyshev interpolation has been restricted to the interval  $[-1, 1]$ , because theorem 06 is most easily stated for this interval. next, scale to general interval  $[a, b]$ .

the base points are moved so that they have the same relative positions in  $[a, b]$  that they had in  $[-1, 1]$ . (1) stretch the points by the factor  $(b - a)/2$ ; (2) translate the points by  $(b + a)/2$  to move the center of mass from 0 to the midpoint of  $[a, b]$ . ie,

$$\cos \frac{\text{odd } \pi}{2n} \mapsto \frac{b-a}{2} \cos \frac{\text{odd } \pi}{2n} + \frac{b+a}{2}.$$

this also changes the numerator of the interpolation error term bc its upper bound will stretch by  $\frac{b-a}{2}$  on each factor  $x - x_i$ . so replace the minimax value

$$\frac{1}{2^{n-1}} \mapsto \frac{\left(\frac{b-a}{2}\right)^n}{2^{n-1}}.$$

#### chebyshev interpolation nodes

on interval  $[a, b]$ ,

$$x_i = \frac{b+a}{2} + \frac{b-a}{2} \cos \frac{(2i-1)\pi}{2n}$$

for  $i = 1, \dots, n$ . the inequality

$$|(x - x_1) \dots (x - x_n)| \leq \frac{\left(\frac{b-a}{2}\right)^n}{2^{n-1}}$$

holds on  $[a, b]$ .

▼ example 11

continues example 07, which used evenly spaced points.

find the four chebyshev base points for interpolation on the interval  $[0, \frac{\pi}{2}]$  and find an upper bound for chebyshev interpolation error for  $f(x) = \sin x$  on the interval.

the chebyshev base points are

$$\frac{\frac{\pi}{2} - 0}{2} \cos\left(\frac{\text{odd } \pi}{2(4)}\right) + \frac{\frac{\pi}{2} + 0}{2}.$$

↓

$$\begin{aligned} x_1 &= \frac{\pi}{4} + \frac{\pi}{4} \cos \frac{\pi}{8}, \\ x_2 &= \frac{\pi}{4} + \frac{\pi}{4} \cos \frac{3\pi}{8}, \\ x_3 &= \frac{\pi}{4} + \frac{\pi}{4} \cos \frac{5\pi}{8}, \\ x_4 &= \frac{\pi}{4} + \frac{\pi}{4} \cos \frac{7\pi}{8}. \end{aligned}$$

the worst-case interpolation error for  $0 \leq x \leq \frac{\pi}{2}$  is

$$|\sin x - P_3(x)| = \frac{|(x - x_1)(x - x_2)(x - x_3)(x - x_4)|}{4!} |f'''(c)| \leq \frac{\left(\frac{\frac{\pi}{2} - 0}{2}\right)^4}{4!2^3} \cdot 1 \approx 0.00198$$

▼ code

```
1 import matplotlib.pyplot as plt
2 import numpy as np
3 import scipy as sp
4 from tabulate import tabulate
5
6 def main():
7     # known
8     x = [0, np.pi/2] # interval
9     n = 4 # roots
```

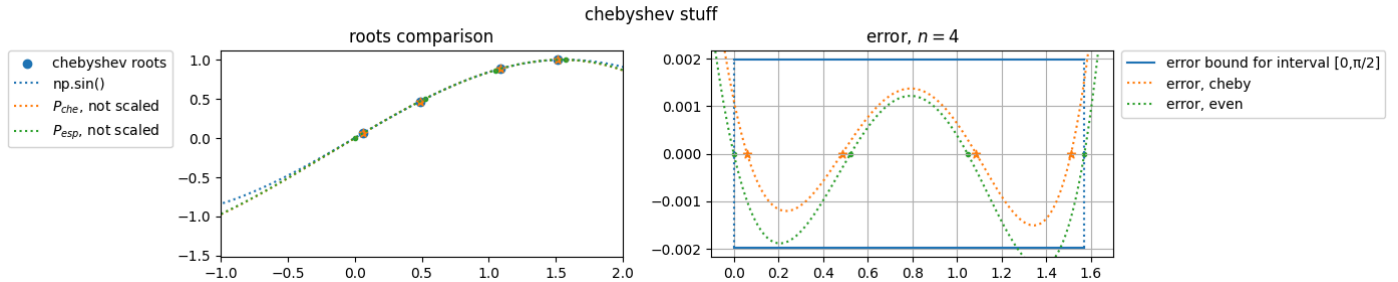

polynomial sine, degree 3:

$$-0.1139 x^3 - 0.06547 x^2 + 1.02 x$$

polynomial sine, degree 3 with chebyshev roots:

$$-0.1143 x^3 - 0.06648 x^2 + 1.023 x - 0.001131$$

x (rad)	np.sin()	P,che	error
1	0.841471	0.840831	0.000639605
2	0.909297	0.909747	0.000449781
3	0.14112	0.142019	0.000899202
4	-0.756802	-0.755505	0.00129727
14	0.990607	0.991736	0.00112865
1000	0.82688	0.826072	0.000807298

## example 12

design a sine key that will give output correct to ten decimal places.

continues example 07.

with error bound  $1e-10$ , calculate number of base points  $n$  required.

$$|sin x - P_{n-1}(x)| = \frac{|(x - x_1) \dots (x - x_n)|}{n!} |f^{(n)}(c)|$$

$$\leq \frac{\left(\frac{\pi-0}{2}\right)^n}{n!2^{n-1}} \cdot 1$$

eventually this coughs up error bound  $\approx 1.224e - 9$  for  $n = 9$  and error bound  $\approx 4.807e - 10$  for  $n = 10$ . with  $n = 10$ , the chebyshev base points on  $[0, \frac{\pi}{2}]$  are  $\frac{\pi}{4} + (\frac{\pi}{4}) \cos(\frac{\text{odd} \pi}{20})$ .
